

Most remaining friction comes from unsupported sites and non-URL user input

Post-mid-Feb error mix + all-time failed-URL input patterns

Where friction is now

Outcome mix of save attempts, post-mid-Feb (2/19-3/18)

Success 52.1%

User 24.5%

External 12.6%

Product 10.0%

92.1% of external errors are unsupported sites

48.4% of user-input errors are blank submits

26.3% of user-input errors are recipe names / search terms

Key takeaway

The two clearest friction drivers are unsupported sites and users not pasting a recipe URL at all.

Only 6.9% of user-input errors look like malformed URLs.

This is primarily a guidance and validation problem, not just a parser problem.

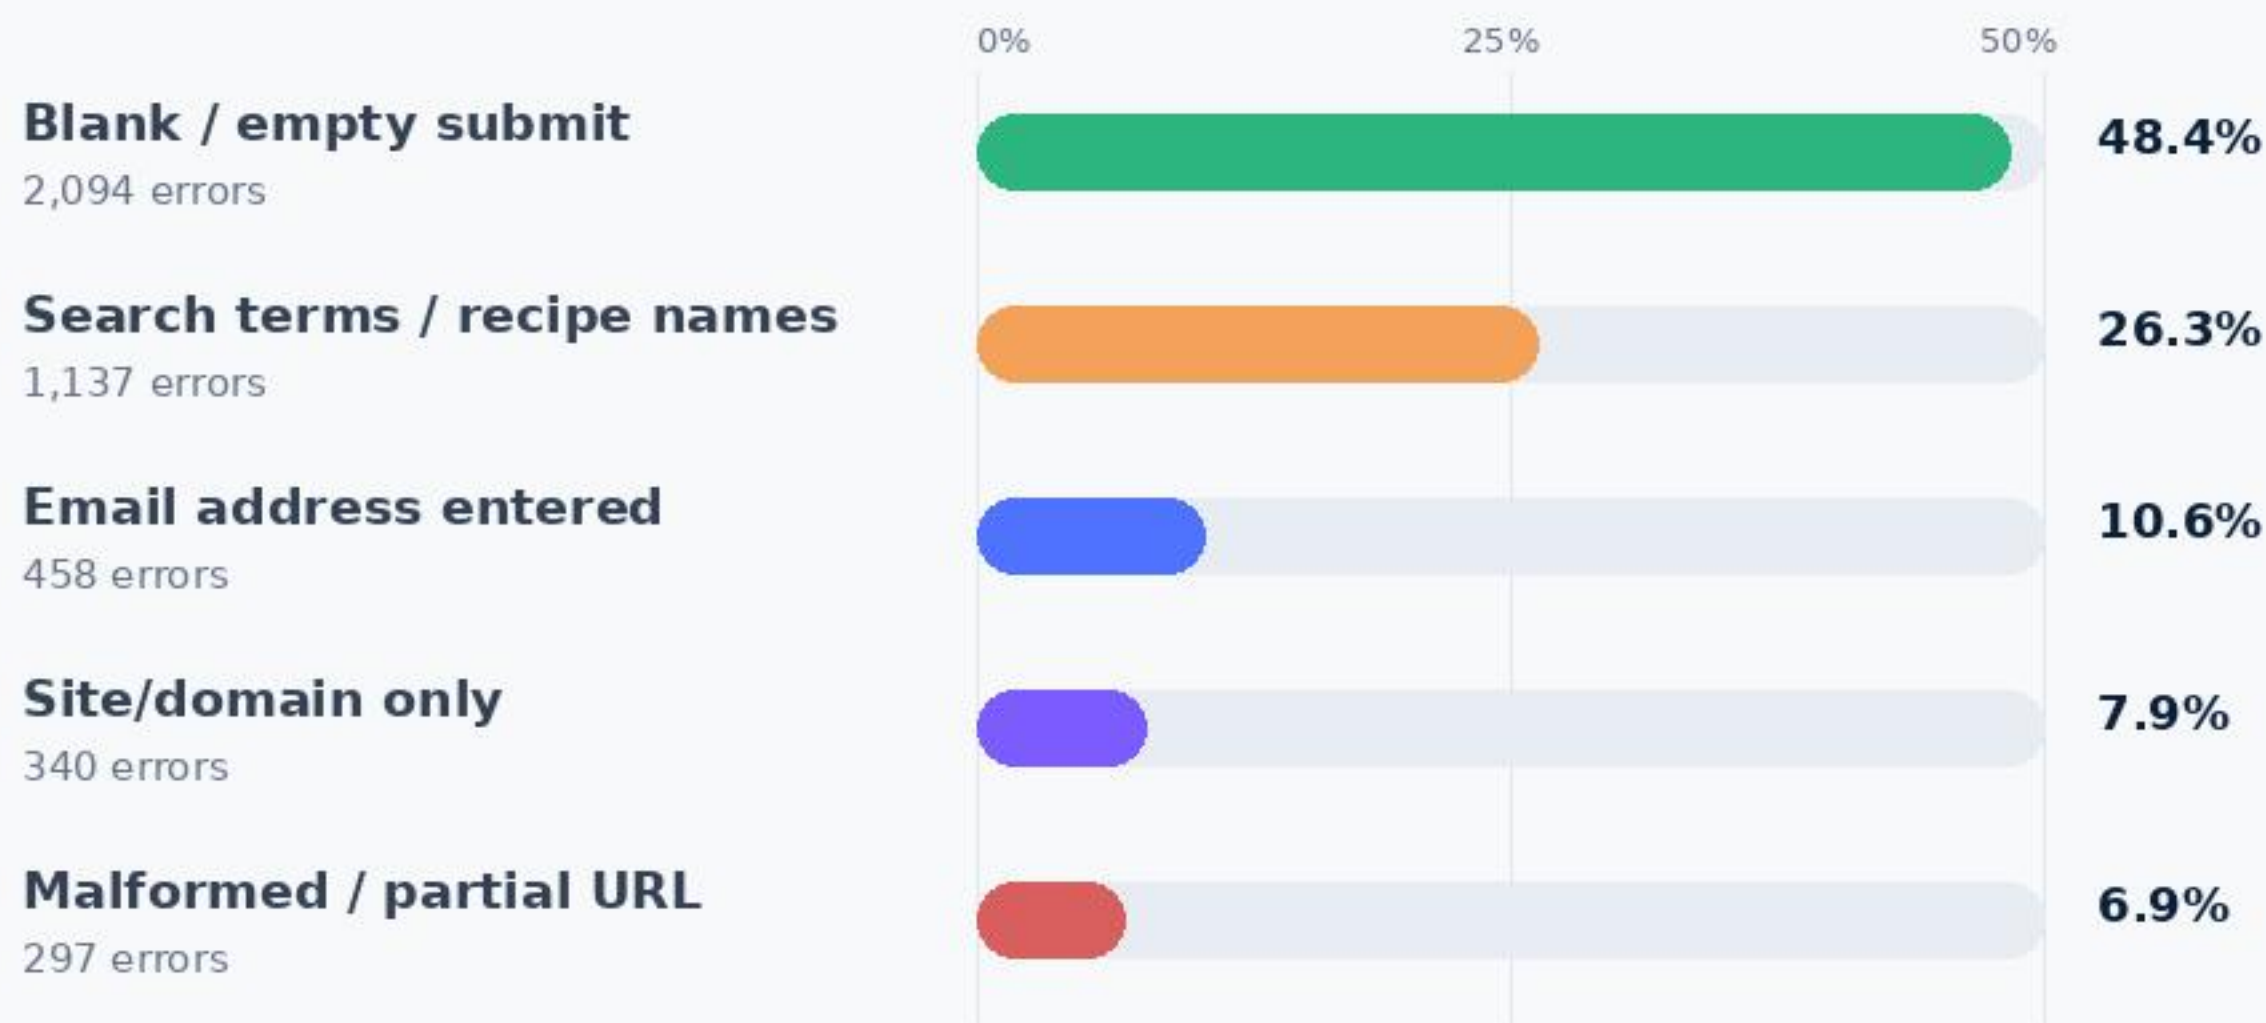

Recommended next moves

- Expand the next 300+ supported sites
- Reduce empty and non-URL submissions
- Add paste-first guidance and inline validation

User-input errors are mostly caused by missing or non-URL input

All-time raw Failed URLs analysis of user_input_error entries only (n = 4,326).

What users are entering instead of a recipe URL

Examples: chicken • goulash • ccabylis@gmail.com • allrecipes.com • https://liveloveandsugar.com

Key takeaway

This is not mainly an email problem or a broken-link problem.

Among nonblank entries, 50.9% are search terms or recipe names rather than a URL.

What this points to

- Disable save on empty submit
- Prompt clearly for a recipe page URL
- Show tailored validation for search terms, emails, domain-only inputs, and malformed URLs
