

Recipe Clipper performance improved in stages

A three-phase view shows improvement through the transition window and into the cleaner post-mid-Feb period.

Average daily save attempt success rate

40.5% -> 47.2% -> 52.1%

Baseline (12/18-1/30) -> transition (1/31-2/18) -> post-mid-Feb (2/19-3/18)

Average save-click time

5.1s -> 4.7s -> 3.8s

Baseline (12/18-1/30) -> transition (1/31-2/18) -> post-mid-Feb (2/19-3/18)

External-brand share of successful saves

79.0% -> 79.1% -> 85.3%

Share of successful saves that are external-brand URLs

What to say on the slide

- 126 supported sites were added on Feb 9 during the transition period
- Performance improves in stages, with gains visible in the transition window and further gains in the trusted post-mid-Feb period
- Use 2/19 onward for trusted user vs product vs external error attribution

Stakeholder takeaway

- We can show steady KPI improvement across three phases instead of forcing a single before/after cut.
- Collections and repeat sessions are still important, but they are not measurable from this export.

Post-mid-Feb error mix points to site coverage as the main scaling constraint

From 2/19 onward, error attribution is the cleanest read of user vs product vs external friction.

Outcome mix of save attempts, post-mid-Feb (2/19-3/18)

● Success 52.1% ● User 24.5% ● External 12.6% ● Product 10.0%

- Product-side issues are about 10.0% of save attempts in the trusted post-mid-Feb period.
- If someone asks about the 21.1% figure, clarify that it is the share of classified failures, not the share of all attempts.

92.1% of external errors are unsupported-site related

84.2% of product errors come from general_fail + bookmark_fail

What we should do next

- Add the next 300+ supported sites
- Keep reducing user-input friction
- Target general_fail and bookmark_fail in product cleanup
